Develop and verify Industrial Controller solutions using BMRA and VMRA on Intel Atom® and Intel® Core™ platforms.

Introduction

The Intel Network and Edge Reference System Architectures (Reference System1) are forward-looking cloud-native reference platforms aiming to ease bare-metal and Kubernetes* cluster product development and deployment for network and edge. The Reference Systems are automatically deployed using Ansible* playbooks that are designed to optimally support diverse use cases across network locations.

This document is a quick start guide to configure the Container Bare Metal and Virtual Machine Reference System Architecture (BMRA and VMRA) on Intel Atom® and Intel® Core™ processor-based platforms for Industrial Controller workloads.

The Reference System has a variety of configuration profile settings for different network traffic workloads. This quick start guide enables the Industrial Controller solution using the On-Premises Software Defined Factory Profile. This document demonstrates the implementation of a Mixed Deployment using the BMRA and VMRA, supporting Industrial Process Automation and Machine Controller use cases by adding an optimized RA Configuration Profile.

This guide highlights the deployment model based on using Intel® Edge Controls for Industrial (Intel® ECI) software for industrial process automation and machine controller deployment mechanism using Reference Systems to transition the industrial control systems to software-defined solutions.

Hardware BOM

Following is the list of the hardware components that are required for setting up Reference Systems:

<table>
<thead>
<tr>
<th>Ansible host</th>
<th>Laptop or server/VM running a UNIX base distribution with internet connectivity</th>
</tr>
</thead>
</table>
| Target platforms (Process Automation) | **Control Plane Node**: Any Intel® Xeon® Gold processor-based platform  
**DCN Node**: 12th Gen Intel® Core™ i7-12700TE processor  
**Remote IO Emulator Node**: 12th Gen Intel® Core™ i7-12700E processor or Intel® Atom® processor x6000 series |
| Target platform (Machine Controller) | 12th Gen Intel® Core™ |
| BIOS | Use the default BIOS settings |

---

1 In this document, “Reference System” refers to the Network and Edge Reference System Architecture.
Software BOM

Following is the list of the software components that are required for setting up Reference Systems:

<table>
<thead>
<tr>
<th>Software BOM</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Edge Controls for Industrial (ECI) services</strong></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td><strong>Container Runtime</strong></td>
</tr>
<tr>
<td><strong>OS</strong></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

For details of the software versions for the **On-Premises Software Defined Factory Profile**, refer to the BMRA/VMRA User Guides listed in the **Reference Documentation** section.

**Getting Started**

**Prerequisites and Deployment Model**

Before starting the deployment, perform the following steps:

- A fresh OS installation is expected on the controller and target nodes to avoid a conflict between the RA deployment process with the existing software packages. To deploy RA on the existing OS, ensure that there are no prior Docker or Kubernetes* (K8s) installations on the servers.
- The hostname must be in lowercase, numerals, and hyphen -. For example: wrk-8 is acceptable; wrk_8, WRK8, Wrk^8 are not accepted as hostnames.
- The platforms are Network Time Protocol (NTP) synced, i.e., they must have the correct date and time.

**Figure 1:** RA Deployment Setup for Factory Process Automation
Installation Flow for RA Deployment

Ansible playbooks are used to deploy the Reference Systems using the `on_prem_sw_defined_factory` profile. Before the playbooks can be run, there are a few steps to prepare the environment and change relevant configuration options.

**System Setup**

1. **Install packages**
2. **Collect information**
3. **Configure servers**

**Download & Install**

1. **Download RA software**
2. **Setup environment**
3. **Install dependencies**

**Configure**

1. **Generate RA profile**
2. **Update inventory**
3. **Update variables**
4. **Apply patches**
5. **Verify configuration**

**Deploy**

1. **Run deployment**

**Validate**

1. **Verify Features**

Figure 2: Industrial Machine Controller Using VMRA

Figure 3: RA Deployment Flow Using Ansible Playbooks

**Step 1 – Set Up the System**

The following steps assume that both the Ansible host and target server are running Ubuntu as the operating system. For RHEL, use `yum` or `dnf` as the package manager instead of `apt`.

**Ansible Host**

1. Install necessary packages (some might already be installed):
   ```
   # sudo apt update
   # sudo apt install -y python3 python3-pip libselinux-python3 openssh-server git
   # pip3 install --upgrade pip
   ```

2. Generate a SSH keypair if needed (check `/root/.ssh/`):
   ```
   # ssh-keygen -t rsa -b 4096 -N "" -f ~/.ssh/id_rsa
   ```

3. Copy the public key to the target servers – controller and worker nodes:
   ```
   # ssh-copy-id root@<target node IP>
   ```

4. Verify passwordless connectivity to the target servers:
   ```
   # ssh root@<target node IP>
   ```
Target Server
1. Install necessary packages (some might already be installed):
   ```
   # sudo apt install -y python3 openssh-server lshw
   ```

Step 2 – Download and Install
Ansible Host
1. Download the source code from the GitHub repository for the Reference System server:
   ```
   # git clone https://github.com/intel/container-experience-kits/
   # cd container-experience-kits
   # git checkout v23.10
   ```

2. Set up Python* virtual environment and install dependencies:
   ```
   # python3 -m venv venv
   # source venv/bin/activate
   # pip3 install -r requirements.txt
   ```

3. Install Ansible dependencies for the Reference System:
   ```
   # ansible-galaxy install -r collections/requirements.yml
   ```

Step 3 – Configure
The On-Premises Software Defined Factory configuration profile (on_prem_sw_defined_factory) is used for both industrial process automation and industrial machine controller deployment.

Industrial Process Automation Configuration
A mixed cluster deployment comprised of VMs and bare metal (BM) hosts is used for the industrial process automation deployment.

Target Host
To enable the TCC feature in the BIOS, navigate to Intel Advanced Menu > Intel® Time Coordinated Computing (Intel® TCC). Set Intel® TCC Mode to <Enabled>. Save your changes and exit the BIOS. The system reboots.

Ansible Host
1. Generate the configuration files:
   ```
   # export PROFILE=on_prem_sw_defined_factory
   # export ARCH=core
   # make examples
   # cp examples/vm/${PROFILE}/inventory.ini .
   # cp -r examples/vm/${PROFILE}/group_vars examples/vm/${PROFILE}/host_vars .
   # cp -r examples/k8s/${PROFILE}/host_vars .
   ```

2. Update the inventory.ini file to match the deployment setup. The values for <hostname> and <IP> must be updated to match the target systems in the BMRA cluster, as shown in Figure 1.
   In this example, we use vm-ctrl-1 and vm-work-1 for the VMRA configuration on the “Control Node”. The difference is we also defined a “DCN” and “Remote-IO” host, which will be a kube_node in the coming mixed cluster.
   ```
   # cd container-experience-kits
   # vim inventory.ini
   [all]
   host-for-vms-1 ansible_host=<Controller IP> ip=<Controller IP> ansible_user=root
   <DCN hostname> ansible_host=<DCN IP> ip=<DCN IP> ansible_user=root
   <Remote-IO hostname> ansible_host=<Remote-IO IP> ip=<Remote-IO IP> ansible_user=root
   localhost ansible_connection=local ansible_python_interpreter=/usr/bin/python3
   [vm_host]
   host-for-vms-1
   [kube_control_plane]
   #vm-ctrl-1
   ```
3. **Update the host_vars filename of BM hosts with the target machine’s hostname:**

   ```
   # cp host_vars/node1.yml host_vars/<DCN hostname>.yml
   # cp host_vars/node1.yml host_vars/<Remote-IO hostname>.yml
   ```

4. **For a mixed BM host, we need to add the VXLAN gateway IP and the VXLAN physical network info to the host_vars/host-for-vms-1.yml. The user is required to set up a proper VXLAN physical network based on their real situation. The subnet must be the same as is used for vm_hosts.**

   **Note:** vxlan_gw_ip must belong to the same subnet as vm_host.

   ```
   # vim host_vars/host-for-vms-1.yml
   vxlan_gw_ip: "172.31.0.101/24"
   vxlan_physical_network: "11.0.0.0/8"
   ```

   The `vxlan_gw_ip` variable defines the VXLAN bridge IP on the mixed BM host. This is also the IP that the cluster will “see” the node. The `vxlan_physical_network` is used to auto select the physical network adapter that will carry on the VXLAN transport. These two parameters are very similar to the ones on VM host host_vars unless only the first VM host requires vxlan_gw_ip.

5. **Update the host_vars/host-for-vms-1.yml with the following settings. This file creates the three VMs on the Control Node with the specified configuration.**

   ```
   # vim host_vars/host-for-vms-1.yml
   vms:
   - type: “ctrl”
     name: “vm-ctrl-1”
     cpu_total: 8
     memory: 20480
     vxlan: 120
   - type: “work”
     name: “vm-work-1”
     cpu_total: 16
     memory: 61440
     vxlan: 120
   - type: “vm”
     name: “vm-1”
     cpu_total: 4
     memory: 61440
     vxlan: 120
   ```

6. **Update the host_vars/<DCN hostname>.yml with the following settings. Here we enable the eci-process-automation and set the DCN node as Codesys OPCUA client.**

   ```
   # Intel ECI (Edge Controls for Industrial)
   intel_eci_enabled: true # if true, deploy Intel ECI
   intel_eci:
   eci-process-automation: true
   eci-manufacturing-equipment: false
   eci-discrete-manufacturing: false
   excat_dp_enabled : true
   ```
7. Update the `host_vars/<Remote-IO hostname>.yml` with the following settings. Here we enable the `eci-process-automation` and set the Remote-IO node as Codesys OPCUA server.

```yaml
## Intel ECI (Edge Controls for Industrial)
intel_eci_enabled: true # if true, deploy Intel ECI
intel_eci:
  eci-process-automation: true
  eci-manufacturing-equipment: false
  eci-discrete-manufacturing: false
excat_dp_enabled: true

opcua_framework :
  codesys_opcua_client : false
  standalone_opcua_server: true

cat_enable: true

## Change the CAT config as per your CPU architecture
cat_define: "llc:0=0x0f;llc:1=0xf0"
cat_affinity: "llc:0=0;llc:1=1,3"
ethercat_mac: ""
```

8. Download and copy the Intel ECI `csl-excat-v3.0.0.tar.gz` file to the Ansible host /tmp folder.

```bash
## Download edge_controls_industrial.zip from eci.intel.com (will redirect to https://edgesoftware.intel.com/edge_controls_industrial, select ubuntu 22.04 and version 3.02 to download)
# Install the package on Ansible host
unzip edge_controls_industrial.zip
cd edge_controls_industrial
chmod +x edgesoftware
./edgesoftware download
cd Edge_Controls_for_Industrial_3.0.2/Edge_Controls_for_Industrial
unzip release-eci_3.0.2.zip
cp ./release-eci_3.0.2/Support/Edge-Orchestration/csl-excat-v3.0.0.tar.gz /tmp
```

### Machine Controller Configuration
VMRA is used for the deployment of the machine controller.

### Ansible Host

1. Generate the configuration files:

```bash
# export PROFILE=on_prem_sw_defined_factory
# export ARCH=core
# make examples
# cp examples/vm/${PROFILE}/inventory.ini .
# cp -r examples/vm/${PROFILE}/group_vars examples/vm/${PROFILE}/host_vars .
```

2. Update the `inventory.ini` file to match your deployment setup. The `<* IP>` must be updated to match the target system in the VMRA cluster, as shown in Figure 2. In this example, we use `vm-1` for the VMRA configuration on the Machine Controller Node.

```bash
# cd container-experience-kits
# vim inventory.ini
```
3. Update the `host_vars/host-for-vms-1.yml` with the following settings:

```yaml
# Set hashed password for root user inside VMs. Current value is just placeholder.
# To create hashed password use e.g.: openssl passw -6 -salt SaltSalt <your_password>
vm_hashed_password: 'xxxxxxxx'
```

```yaml
# Fill your physical network mask to this field.
vxlan_physical_network: "xxxxxxx"
```

```yaml
# Fill your CAT config to these two fields. Example refers to the vm configuration below.
cat_define: "llc:0=0x0f;llc:1=0xf0"
cat_affinity: "llc:0=0;llc:1=1,3"
```

```yaml
# Update "vms" list with generic VM config used for ECI. Use example below as a guide and
# follow the comments to change the resources.
# Example assumes that there is only one numa on the host machine.
vms:
- type: "vm"
  name: "vm-1"
  cpus: '2,3'
  numa: 0
  cpu_total: 2
  memory: 4096
  vxlan: 120
  pci:
    - "03:0.0.0"
```

4. Update the `host_vars/vm-ctrl-1.yml` filename `vm-1`:

```bash
# mv host_vars/vm-ctrl-1.yml host_vars/vm-1.yml
```

5. Disable Kubernetes in `group_vars/all.yml`:

```bash
# vim group_vars/all.yml
kubernetes: false
```

The following group var configurations are common to both Process Automation and Machine Controller use cases:

1. Add the CPU SKU number of the controller node to the `group_vars/all.yml`:

```bash
# vim group_vars/all.yml
unconfirmed_cpu_models: ["<ADD CPU SKU number here, eg:6238L>"]
```
2. Add the Intel® ECI repository link to `group_vars/all.yml`. Contact eci-support@intel.com for information on how to access this repository.

```bash
# vim group_vars/all.yml
intel_eci_repo: https://eci.intel.com
```

3. If the server is behind a proxy, update `group_vars/all.yml` by updating and uncommenting the lines for `http_proxy`, `https_proxy`, and `additional_no_proxy`.

```bash
# vim group_vars/all.yml
## Proxy configuration ##
http_proxy: "http://proxy.example.com:port"
https_proxy: "https://proxy.example.com:port"
additional_no_proxy: ".example.com,mirror_ip"
```

4. (Required) Apply required patches for Kubespray:

```bash
# ansible-playbook -i inventory.ini playbooks/k8s/patch_kubespray.yml
```

5. (Optional) It is recommended that you check the dependencies of components enabled in `group_vars` and `host_vars` with the package dependency checker:

```bash
# ansible-playbook -i inventory.ini playbooks/preflight.yml
```

6. (Optional) Verify that Ansible can connect to the target server by running the following command and checking the output generated in the `all_system_facts.txt` file:

```bash
# ansible -i inventory.ini -m setup all > all_system_facts.txt
```

---

### Step 4 – Deploy

**Ansible Host**

The Reference System can be deployed by using the following command:

**Industrial Process Automation Deployment**

```bash
# ansible-playbook -i inventory.ini playbooks/on_prem_sw_defined_factory.yml --flush-cache
```

**Machine Controller Deployment**

```bash
# ansible-playbook -i inventory.ini playbooks/vm.yml -e "eci_package=eci-manufacturing-equipment"
```

**Note:** The `eci_package` supports three packages: `eci-process-automation`, `eci-manufacturing-equipment`, `eci-discrete-manufacturing`. The `intel_eci` field in `vm-1.yml` can also specify the Intel ECI packages installed. However, the package specified by `-e eci_package=` overwrites the `intel_eci` field in `host-for-vms.yml`.

**Cleanup:** If the playbook fails or if you want to clean up the environment to run a new deployment, you can optionally use the provided Cluster Removal Playbook to remove any previously installed Kubernetes and related plugins.

```bash
# ansible-playbook -i inventory.ini playbooks/redeploy_cleanup.yml
```

---

### Step 5 – Validate

**Industrial Process Automation Verification**

Below are the steps to validate the Industrial Process Automation use case.

**Ansible Host**

1. To interact with the Kubernetes CLI (kubectl), start by connecting to the controller VM node in the cluster, which can be done using the following commands:

```bash
# ssh root@vm-ctrl-1
```

2. Once connected, the status of the Kubernetes cluster can be checked:

```bash
# kubectl get nodes -A
```
Note: The `intel-adl-tank` is the DCN node and the `intel-tank-rpl` is the Remote_IO node.

3. The ExCAT feature can be verified on the DCN and Remote-IO nodes:

```
# kubectl describe node <node_name> | grep exact
```

4. Launching of industrial services was completed in Step 4, and the Open Platform Communications United Architecture (OPC UA) Client Human Machine Interface (HMI) can be accessed through a browser at `http://<DCN_IP_ADDRESS>:8080`. Configure and Run OPC UA Client Benchmark is a complete guide on the HMI and how to connect it to the OPC UA server instance.

![Example of an HMI Dashboard for the OPC UA Client](image)

Figure 4: Example of an HMI Dashboard for the OPC UA Client
Machine Controller Verification

To run the machine controller app, use PLCopen sample applications. The PLCopen sample applications are isochronous. Following are the steps to validate the Industrial Machine Controller use case.

1. To interact with the application, start by connecting to the controller VM host terminal console using SSH:
   ```
   # ssh root@host-for-vms-1
   ```

2. Then connect to the controller VM-1 terminal console using SSH:
   ```
   # ssh root@vm-1
   ```

3. In case the EtherCAT servo is not available, run the following application:
   ```
   # sudo /opt/plcopen/multi-axis-monitor
   ```

4. In case the EtherCAT servo is ready, use these steps to run the machine controller:
   ```
   # sudo /opt/plcopen/ethercat sl
   # sudo taskset -c 1 /opt/plcopen/six_rtmotion_demo -n /opt/plcopen/inovance_six_1ms.xml -i 1000
   ```

Additional feature verification tests can be found here:
